Learn more: Abstract The model is used to illustrate the operation of the nonlinear feedback mechanism in the heart, a mechanism by which the heartbeat is influenced by the aortic pressure. When the frequency of the heartbeat changes, the left ventricle and left atrium increase and decrease in length, respectively, and the two organs respond nonlinearly to the aortic pressure. The model accounts for the effects of nonlinearity in the linear systems model, and describes the nonlinear interactions among the two organs. The main effect of nonlinearity is that the lengths of the two organs are no longer equal, but the lengths ratio (the length of the right ventricle over the left atrium) is not affected, since the model does not represent linear systems. The model equations have been solved numerically using a finite difference scheme for a sinusoidal input of unit amplitude. The results of the numerical solution are compared to those obtained by the single-mode oscillator method. The heartbeat is found to have a frequency that is an increasing function of the aortic pressure. Python module inside a package.
