Pricing is annual, with prices beginning at \$100,000 and rising to \$1,000,000. References IP Phone Category:Telephony equipmentSpontaneous development of bronchiolitis obliterans after lung transplantation. Bronchiolitis obliterans (BO) is one of the main complications after lung transplantation. It is a progressive fibroproliferative disease and has a devastating impact on prognosis and quality of life. Patient characteristics, treatment, and therapeutic interventions are essential elements in the multifactorial pathogenesis of BO. Bronchiolitis obliterans is diagnosed on posttransplantation computed tomographic scan, the standard procedure for detection of this disease. A discrepancy between the presence or absence of BO, as determined by image and endoscopically correlated histologic investigation of the lung allograft, might be present. Bronchiolitis obliterans appears to arise spontaneously, in the absence of known causes. In a follow-up of our lung transplant cohort, 66 cases of BO have been diagnosed. Spontaneous formation of BO occurred in 37% of all primary lung transplantations. The median time to diagnosis was 63.0 months after transplantation. Fifty-nine percent of the patients developed BO as the only complication of lung transplantation. One-half of the patients died within 12 months after diagnosis.The corpus callosum not only controls central information processing, but it might also be crucial for a left-hemispheric ability to switch attention to the left hemifield, according to a new study. The hypothesis of extra-callosal pathways for spatial attention was first proposed by Merzenich and Van Essen (1980), who noted that memory, spatial attention and visual imagery share a common processing pathway. If spatial attention is associated with the right hemisphere, then lesions of the corpus callosum would impair the ability of the brain to switch attention to the left hemifield. " 82138339de
